Drying is essential for the effective banking of orthodox seeds. Seeds should be dried to approximately 15% equilibrium relative humidity (eRH) before long-term storage. This allows the seeds to tolerate freezing, increases longevity in storage, prevents attack by pests and pathogens, and postpones germination.

The choice of drying method depends on the projected yearly seed intake. A purpose-built dry room may be the most suitable option for drying large quantities of seeds (see Technical Information Sheet_11). This information sheet describes various lower-cost drying options that may be more appropriate for small-scale seed banks.

**Incubator-drying**

Cooled incubators are usually used for germination testing, but can also provide an ideal alternative for small-scale seed drying. A cooled incubator set at 18ºC can achieve an average internal relative humidity (RH) of 15% RH. Experiments at the Millennium Seed Bank (MSB) showed that a cooled incubator can dry 10kg of freshly harvested seed, with an initial eRH of 99%, to around 15% eRH after approximately 4 weeks. The incubator operates satisfactorily in external environmental conditions of 16ºC to 45ºC and 5% to 75% RH.

**How do cooled incubators work?**

The temperature of a cooled incubator is controlled by a standard vapour compression refrigeration system, which constantly cools the internal chamber, together with a heater, which cuts in and out to maintain the desired temperature. Moisture condenses on the cooling coils due to their low temperature. Every six hours, the system begins a 30-minute defrost. Moisture drains from the cooling coils and out of the chamber, evaporating from a tray on top of the hot compressor. The internal relative humidity (RH) is usually 7% to 10%, rising to 65% during the defrost cycle. This gives an average seed eRH of 15%, which is ideal for long-term storage.

Varying the temperature settings of the incubator will produce different RH conditions.

**Using a cooled incubator to dry seeds**

Put seed collections into cotton bags and spread these out on the shelves. Seeds held in trays will take longer to dry because air movement is restricted. You can add seed collections on a daily basis, without affecting the overall performance of the dryer.

Drying times will vary between species, depending on seed size, structure and permeability of the seed coat. Monitor seed eRH weekly during drying using a hygrometer (see Technical Information Sheet_05). When an eRH of 15% has been achieved, remove the collection, seal in an air-tight container (see Technical Information Sheet_06) and store in a freezer or cold room.

The incubator can be used for germination testing once the seeds have been dried and stored, simply by adjusting to an appropriate temperature and photoperiod (by changing the lighting).
Drying with desiccants

Any hygroscopic substance that can be dried can act as a desiccant and absorb moisture from the surrounding air. If moist seeds are sealed in a container with a dried desiccant, the desiccant will dry the air, which in turn dry the seeds. Silica gel is commonly used to dry seeds. Other desiccants that work effectively include charcoal and seeds such as rice or maize.

Choose a non-porous container of appropriate size, with a tightly fitting lid which will seal effectively. Use plastic boxes, buckets with air-tight lids, or a sealed, heavy-duty plastic sack.

Using silica gel to dry seeds

Silica gel is available as clear beads or as indicating beads which change colour according to moisture status. Methyl violet indicator is dark green when wet and orange when dry. The colour change from wet to dry occurs either side of a 20-25\% RH boundary. The silica gel can be dried and re-used as a desiccant until it no longer absorbs moisture.

- Dry the seeds to ambient conditions before you start.
- Fill the container approximately 20\% by volume with oven-dried silica gel beads. A mix of 10\% indicating to non-indicating beads is recommended.
- Put seed collections, held in cloth or paper bags, into the container, ensuring adequate air circulation.
- Maintain a minimum weight ratio of 1:1 silica gel to seed material.
- Place the drying container out of direct sunlight, in a cool place.

When the seeds are dry, seal the collection in an air-tight container and store in a freezer or cold room. Add a dry indicating silica gel sachet to the collection to monitor moisture status during storage.

Regenerating the silica gel

Re-dry the silica gel when the RH rises above 15\%, or the indicator beads are coloured green. Remove the silica gel from the container, place in a shallow metal tray and dry gently in an oven at no more than 100\°C, for 1-2 hours (or until green beads turn orange). If the beads are over-heated, this may damage the colour-change properties of the indicator. Cover the tray and allow the silica gel to cool for 15 minutes, then return to the drying container.

Below: “Box-dryer” - plastic box with seed collections in cloth bags, placed on a plastic mesh above dried silica gel
Using charcoal to dry seeds

Natural or lump-wood charcoal is widely available and can be used as a low-cost alternative to silica gel. Dried charcoal absorbs moisture from the air if sealed in a container with seeds. The use of charcoal as a desiccant is a more flexible and less precise approach than using silica gel. The charcoal can be re-used until it fails to absorb moisture.

- Dry the charcoal before use. Spread out on a metal tray and leave to dry in the sun, or dry at a low heat in an oven, then cover the tray (preventing moisture uptake) and allow to cool.
- Place the dried, cooled charcoal into a sealable container.
- Spread seeds above the charcoal in the drying container, on a sheet of newspaper or in porous collecting bags.
- The wetter the seeds, the more charcoal is required. Use a minimum weight ratio of 3:1, charcoal to seed material. If possible, dry the seeds to ambient conditions first. This will remove some moisture and mean that less charcoal will be needed.
- Seal the drying container and keep in a cool place (avoid direct sunlight).
- Make weekly measurements of the moisture status of the charcoal, by sealing a small quantity into a separate air-tight container, such as a glass jar, with a moisture indicator. The charcoal will equilibrate with the air inside the container and the moisture indicator will reflect the moisture status of the air.
- Monitor the moisture status of the seeds by adding a low-cost moisture indicator to each seed collection bag (see Technical Information Sheet_07).

The seeds may take at least one month to dry, depending on the initial moisture status of the seeds, the volume of the collection, the size and structure of seeds and the moisture status of the charcoal. Small seeds will dry more quickly so will need frequent monitoring.

Once the seeds are dry, place each collection in an air-tight container to prevent moisture from being re-absorbed, and store in a cool place.

RBG Kew’s Mini Seed Bank

The Mini Seed Bank is designed for gardeners or allotment-holders wishing to save their seeds, but can also be employed by small-scale conservation projects. The simple instructions follow similar principles to those adopted by large-scale seed banks.

This kit has been developed for the collection, processing, drying and storage of seeds, through the MSB’s continuing studies into improved seed conservation technology.

The main components of the kit are a high quality polythene box and a reusable silica gel desiccant with coloured indicating beads. The box acts both as a drying chamber and as the ‘seed bank’ at the end of the collecting season. Indicating silica gel sachets are also included so that the seed drying process can be monitored, ensuring that the seeds are only stored once they have been sufficiently dried.
Drying cabinets

MSB partners at Victoria Royal Botanic Gardens, Australia, have limited work space and a moderate throughput of seed collections. The seed bank processes about 100 species per year with a minimum of 4,000 seeds per species. They have opted for a purpose-built drying cabinet instead of a dry room.

The two-door drying cabinet was constructed by a local refrigeration manufacturer. It has a built-in cooling unit and is attached to a dehumidification unit (MCS300, supplied by Munters). Moist air is removed by connecting the outlet to the seed bank’s duct system.

Seed collections of most species achieve a moisture status below 20% eRH within a few weeks in this drying cabinet, when set at 15% RH and 15°C. The drying time will depend on seed size and collection volume. The largest seeds in the Victorian flora are under 10mm diameter, although some fruits, such as those of Banksia, are as large as 150 × 80mm.

The advantage of this drying cabinet system is that it is relatively cheap to buy, run and maintain, and can easily be moved around within the seed bank. A constant temperature and humidity is generated throughout the cabinet.
